The SPO Wetland Characterization is a planning tool to help identify significant wetland resources and affiliated upland systems. This map identifies wetlands that are likely to provide flood flow control, sediment retention, wetlands-related plant and animal habitat, and finfish habitat. It also identifies wetlands that may have value for educational and research opportunities. There are additional and important wetland functions and values that are not depicted by this map. In addition, smaller wetlands, particularly vernal pools, drier-end forested wetlands, as well as the extent of larger wetland are known to be underrepresented in the NWI data used to create this map.
